Introduction to SBSE (2/2)

Shin Yoo

SEP592, Summer 2020, School of Computing, KAIST

Teacher: add numbers from 1 to 100!

Young Gauss: 1 + 2 + ... + 50 + 100 + 99 + ... + 51 = 101 + 101 + ... + 101 = 101 * 50 = 5050

Computer: Is it 782? Teacher: Nope. Computer: Is it 783? Teacher: Nope.

Computer: Is it 5050? Teacher: Yes (finally...)

Let's start with terms.

heuristic | hju(ə) rıstık |

adjective

- enabling a person to discover or learn something for themselves. a 'handson' or interactive heuristic approach to learning.
- Computing proceeding to a solution by trial and error or by rules that are only loosely defined.

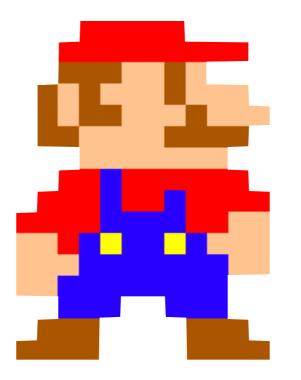

meta- | 'metə | (also met- before a vowel or h)

combining form

- 1 denoting a change of position or condition: *metamorphosis*.
- 2 denoting position behind, after, or beyond: metacarpus.
- **3** denoting something of a higher or second-order kind: *metalanguage* | *metonym*.
- 4 Chemistry denoting substitution at two carbon atoms separated by one other in a benzene ring, e.g. in 1,3 positions: *metadichlorobenzene*. Compare with ORTHO- and PARA-¹ (SENSE 2).
- 5 Chemistry denoting a compound formed by dehydration: *metaphosphoric acid*.

Meta-heuristic

- Strategies that guide the search of the acceptable solution
- Approximate and usually non-deterministic
- Not problem specific
- Smart trial and error

Let's play Super Mario Bros.

http://arxiv.org/pdf/1203.1895v3.pdf

Classic Nintendo Games are (Computationally) Hard

Greg Aloupis*

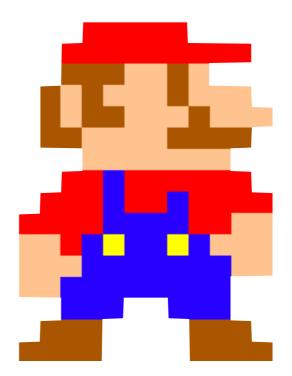

Erik D. Demaine[†] Alan $Guo^{\dagger\ddagger}$

Giovanni Viglietta[§]

February 10, 2015

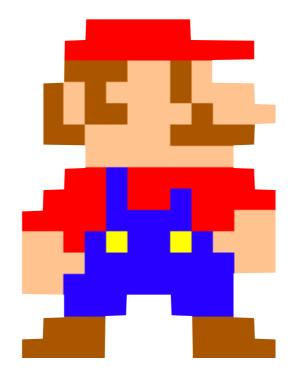

Player A

- Read the game manual to see which button does what.
- Google the level map and get familiar with it.
- Carefully, very carefully, plan when to press each button, for how long.
- Grab the controller and execute the plan.

Player B

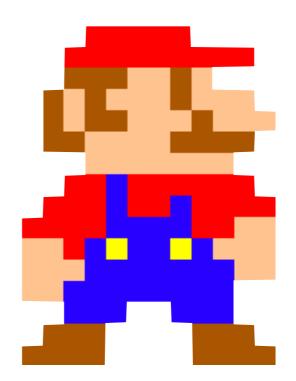

- Grab the controller.
- Play.
- Die.
- Repeat until level is cleared.

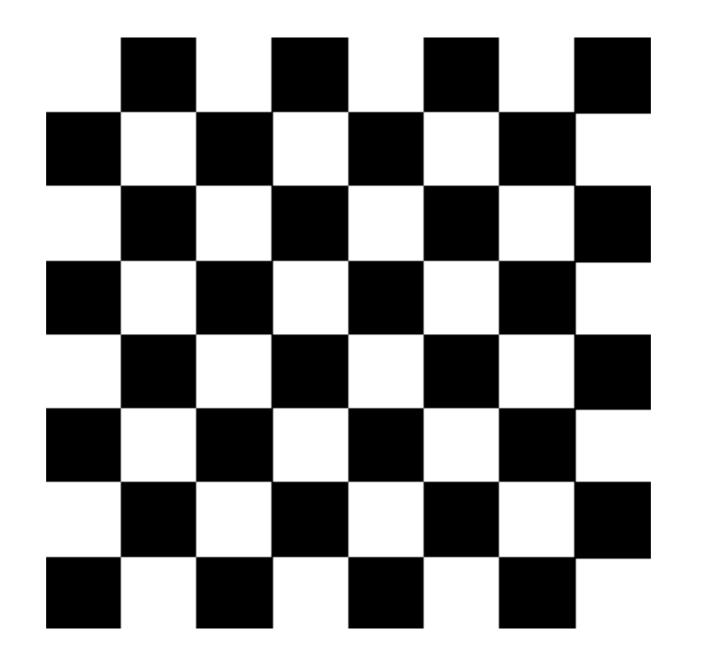

Intelligence lies in how differently you die next time.

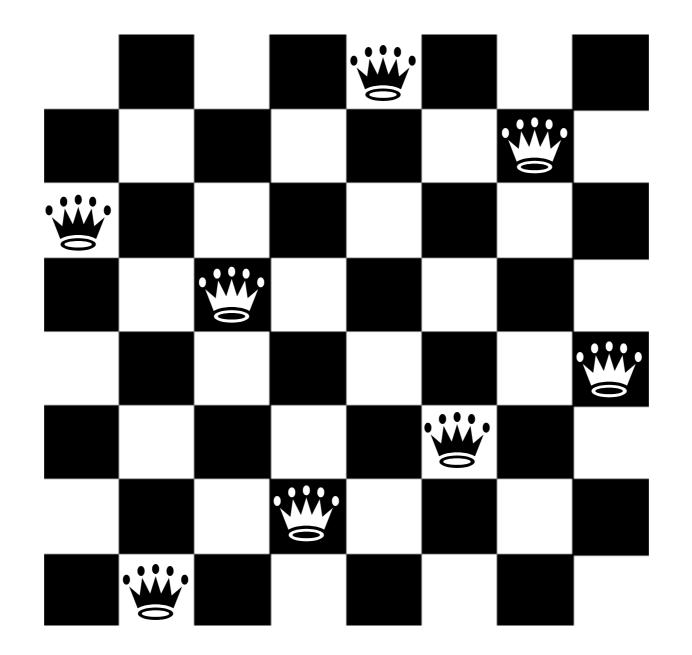

Mario analogy goes a long way

- You make small changes to your last attempt ("okay, I will press A slightly later this time").
- You combine different bits of solutions ("Okay, jump over here, but then later do not jump over there").
- You accidentally discover new parts of the map ("Oops, how did I find this secret passage?")

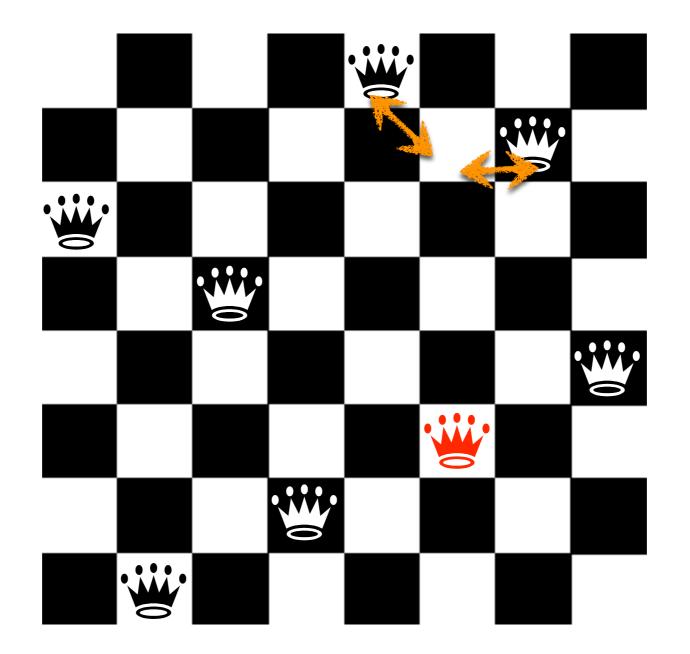

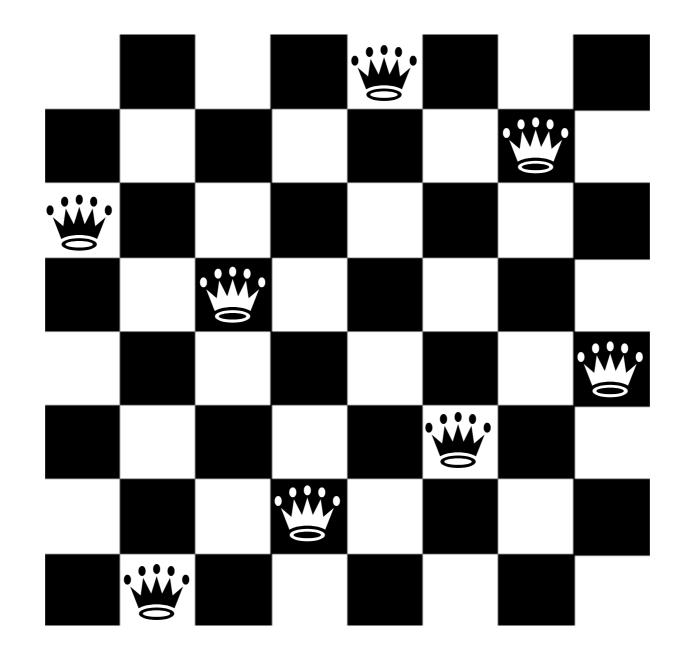

Place 8 queens on a chessboard so that no pair attacks each other.

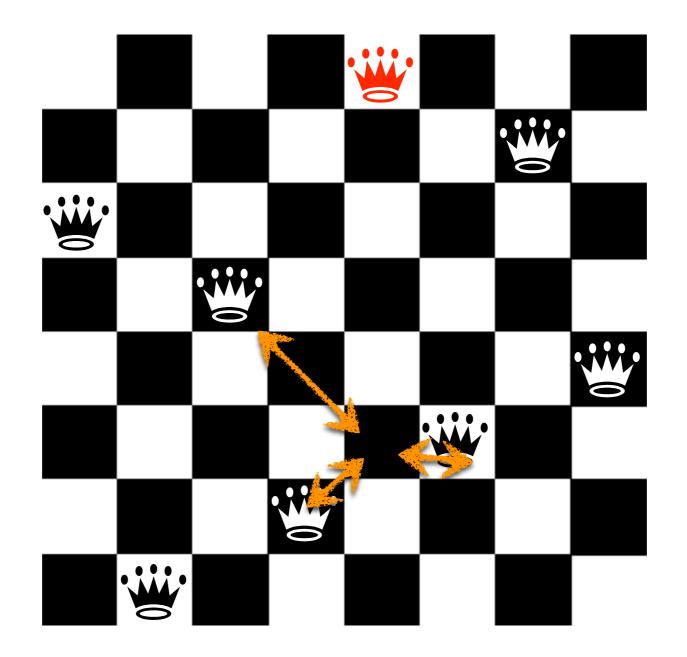

Perfect solution: score 0

Two attacks: score -2

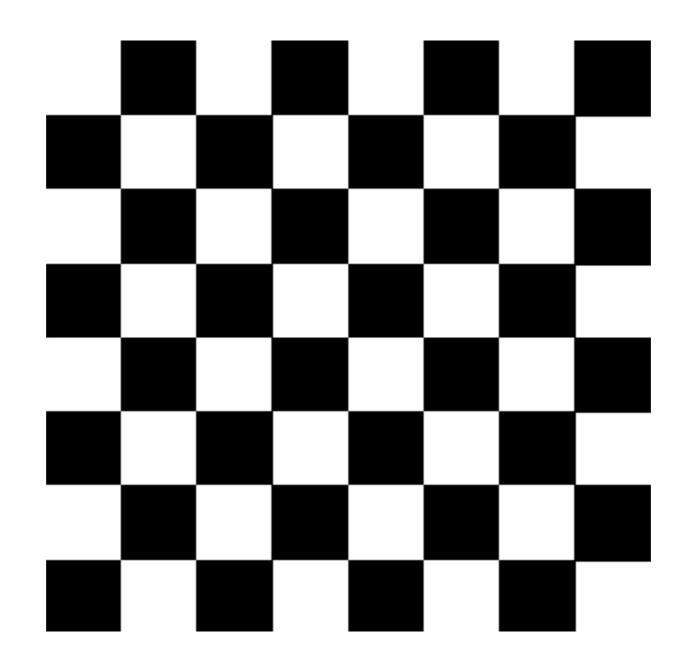

Three attacks: score -3

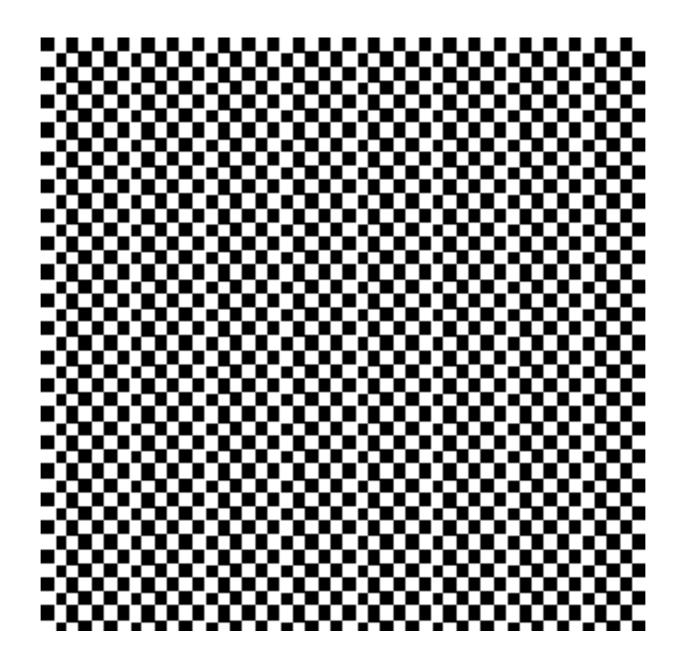

Two Approaches

Build an algorithm that produces a solution to the problem by placing one piece at a time

Build an algorithm that compares two solutions to the problem; try different solutions, keep the better one, until you solve the problem Does it scale?

44 Queens Problem

Place 44 Queens on the board with no attack.

10¹² Queens Problem

Place 10¹² Queens on the board with no attack.

Trial and Error

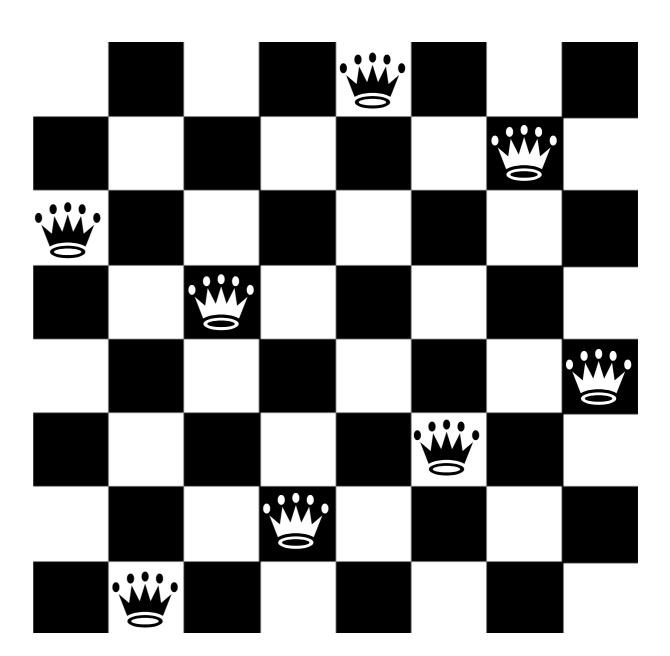

- Abundance of computational resources means many domains are adopting (knowingly or not) a similar approach.
 - Corpus-based NLP
 - Go (the only competitive AI players are based on Monte-Carlo Method)
 - Many application of machine learning

Key Ingredients

- What are we going to try this time? (representation)
- How is it **different** from what we tried before? (operators)
- **How well** did we do this time? (fitness/objective function)
- Minor (but critical) ingredients: constraints

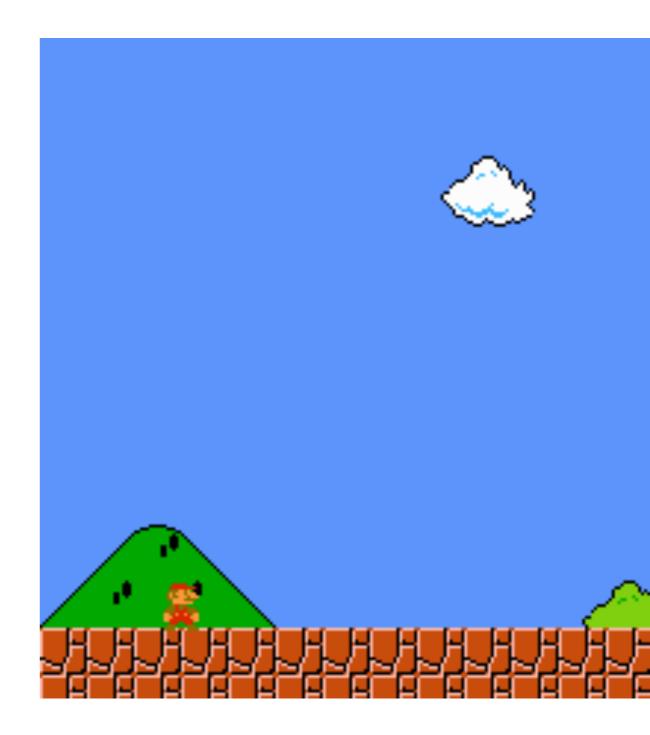

8 Queens Problem

- Representation: 8 by 8 matrix
- Operators: generate one valid board position from the current position, following the rule about Queen's movement
- Fitness function: number of attacks (to be minimised)

Super Mario Bros.

- Representation: a list of (button, start_time, end_time)
- Operators: change button type in one tuple, increase/ decrease start_time or end_time
- Fitness function: the distance you travelled without dying

Universal Viewpoint

- There are many algorithms in computational intelligence; you do need to learn individual algorithms in detail.
- However, I also want to communicate a frame of thinking, not only individual algorithms.
- The tuple of (representation, operators, fitness function) can be a universal platform to understand different classes of algorithms.
- We will revisit individual algorithms, using this tuples.

Design dictates solution

- Incorrect representation: what happens if we use (button, pressed_time) instead?
- Using wrong operators: what happens if we decrease/ increase start_time and end_time by 5 seconds?
- Missing constraints: what happens if we swap the order of two tuples?
- Measuring the wrong fitness: what happens if we use the time elapsed until death? Or the final score?

Exploitation vs. Exploration

- Exploitation: if a candidate solution looks promising, optimisation should focus on that particular direction. However,
- Exploration: unexplored solution space may contain something *much better*.
- How to balance these two is critical to all learning/ optimisation algorithms.

Machines are Dumb and Lazy

- Like human, they will do the minimum work that passes your criteria, i.e. design of the optimisation problem.
- Not because of their work ethic, but because of the fact that, usually, minimum work is the easiest to find solution.

Case Study: GenProg

- GenProg uses stochastic optimisation to modify existing faulty software code, until it passes all tests.
- We can only tell it to try until it passes all tests, not until the program is correct.

Anecdotes borrowed from Wes Weimer's SSBSE 2013 Keynote: https://www.cs.virginia.edu/~weimer/p/weimer-ssbse2013.pdf

Things GenProg Did...

- nullhttpd: test case for POST function failed; GenProg removed the entire functionality.
- **sort**: test required output to be sorted; GenProg's fix was to always output an empty set.
- Tests compared output.txt to correct_output.txt; GenProg deleted correct_output.txt and printed nothing.

Current State of the Art

- Low hanging fruits almost gone: "I applied algorithm X to problem Y" no longer counts.
- Metric-based optimisation (where fitness equals an existing SE metric) is starting to be criticised. Compare the following two papers:
 - M. Harman and J. Clark. Metrics are fitness functions too. In 10th International Software Metrics Symposium (METRICS 2004), pages 58– 69, Los Alamitos, California, USA, Sept. 2004. IEEE Computer Society Press.
 - C. Simons, J. Singer, and D. R. White. Search-based refactoring: Metrics are not enough. In M. Barros and Y. Labiche, editors, Search-Based Software Engineering, volume 9275 of Lecture Notes in Computer Science, pages 47–61. Springer International Publishing, 2015.

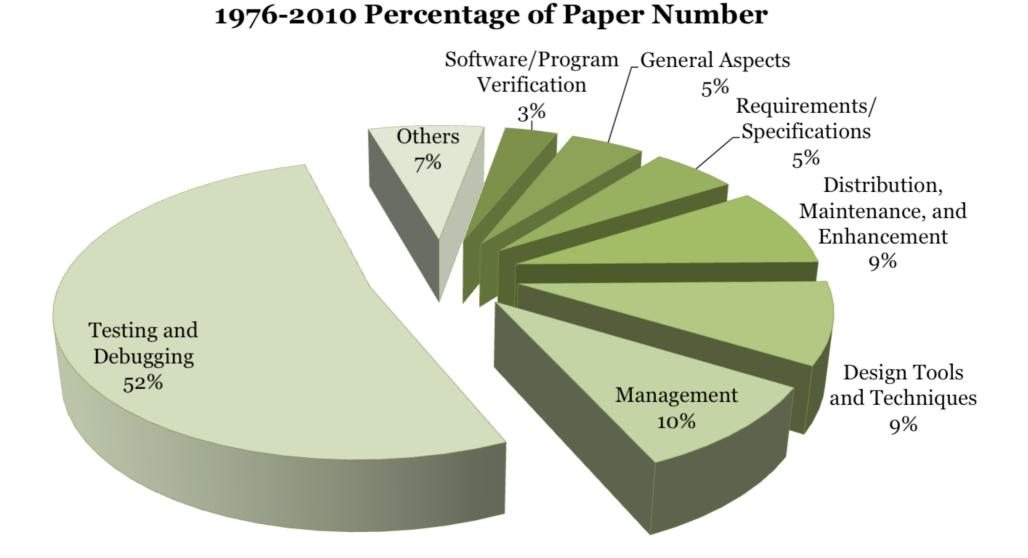

How to do better?

- Try to learn from human engineers more.
- Eventually, solutions from SBSE should be adopted because humans accept it, **not** because the fitness value is above an arbitrary cut-off point X.
- Turing-test as fitness function!

Expected Learning Outcome

- Understand basic metaheuristic algorithms; learn how to implement and adapt one to a given problem.
- Embrace metaheuristic optimisation as a valid tool for software engineers.
- Gain knowledge of the literature; learn case studies for various software development lifecycle stages.

Problem Domains

Structural Testing

- Take CS453 Automated Software Testing:)
- Intuitively: define the input constraints required to achieve structural coverage; solve the constraints using optimisation.
 - Symbolic execution + constraints solver
 - Dynamic analysis + metaheuristic optimisation
- Either way, huge advances in the last decade.
 - Clearly defined fitness function, industry demand (at least on achieving coverage)

Oracle Problem

- Coverage is not enough: "was the last execution correct?"
- Test oracle tells you whether the observed execution was correct or not
- Formal specification can serve as one; manual inspection by human can serve as one. But how do we automatically generate oracles?
- We want to test the code; we automatically generate test from the code; we want to check whether the test passed; we automatically generate test oracle from the co... wait a minute!
- This is a very hard problem; one which the state of the art does not know how to solve.

Testing non-functional properties

- Worst-Case Execution Time Analysis: strictly necessary for certain embedded systems (e.g. airbag controller), very hard to do statically; genetic algorithm has been very successful.
 - J. Wegener and M. Grochtmann. Verifying timing constraints of real-time systems by means of evolutionary testing. Real-Time Systems, 15(3):275 – 298, 1998.

Requirements Engineering

- Next Release Problem: given cost and benefit (expected revenue) for each features, what is the best subset of features to be released for budget B?
 - 0-1 Knapsack (NP-complete)
 - But release decisions are more political than NPcomplete.
- Sensitivity Analysis: requirements data are usually estimates; which estimation will have the largest impact on the project, if it is off by X%?

Project Management & Planning

- Quantitatively simulate and measure the communication overhead (linear? logarithmic?)
- Robust planning: search for the tradeoff between overrun risk, project duration, and amount of overtime assignment

Design/architecture/ refactoring

- Cluster software models to achieve certain structural properties (cohesion/coupling).
- Ironically, SBSE has also been used to analyse refactoring metrics: metric A and B both claim that they measure the same concept - optimising for A resulted in worse value of B, and vice versa :)

Genetic Improvement

- Given a source code, can we automatically improve its non-functional properties (such as speed)?
- Genetic Programming has been successfully applied to make genomesequencing software 70 times faster. 70!
 - W. Langdon and M. Harman. Optimizing existing software with genetic programming. Transactions on Evolutionary Computation, 19(1):118–135, 2015.
- Evolve a specialised version of MiniSAT solver for problem classes.
 - J. Petke, M. Harman, W. B. Langdon, and W. Weimer. Using genetic improvement and code transplants to specialise a C++ program to a problem class. In proceedings of the 17th European Conference on Genetic Programming, volume 8599 of LNCS, pages 137–149. Springer, 2014.

Code Transplantation

- Software X has feature A, which you want to have in software Y. Can we automatically extract and transplant feature A from X to Y?
 - E. T. Barr, M. Harman, Y. Jia, A. Marginean, and J. Petke. Automated software transplantation. In Proceedings of the 2015 International Symposium on Software Testing and Analysis, ISSTA 2015, pages 257–269.

Summary

- Key ingredients to SBSE: representation, operators, fitness function.
- Design dictates solutions.
- Applications across all software development lifecycle activities, and beyond.
